

a mRNA stability: every encoder reads one coding sequence

Each codon fixes one amino acid, so the grid is given by the genetic code: no model has to learn it. Encoders that truncate at 1,022 nt cover only the start of the grid.

b GTEx: each modality is a different molecule

No position-by-position correspondence links the window to the transcript or the protein, so there is no shared grid: fusion on GTEx uses cross-attention or pooled vectors.
